Worksheet 5: Cryptography

- 1. Compute 2²²² mod 101.
- 2. Our goal is to come up with a *code* modulo 101; that is, we want to send a message consisting of 2-digit numbers, and we'd like to encode it in such a way that only our friends can decode it. The first coding scheme we'll describe is due to Diffie and Hellman. It is a *public-key code* because part of the code is known to everyone. Here's how it works: you and your friend choose a prime number p (such as 101) and an integer g between 2 and p-1. Both of these numbers are public (so, e.g., you two can safely discuss these numbers on the phone or over the internet—if someone wiretaps you, no problem). Now you *secretly* choose an integer m, and your friend *secretly* chooses an integer n. You compute $g^m \mod p$ and tell your friend the result. Your friend computes $g^n \mod p$ and tells you the result. The secret key that you both can use is

$$s \equiv g^{mn} \equiv (g^m)^n \equiv (g^n)^m \bmod p.$$

The last two equalities explain why both you and your friend can easily compute s. You can now use s to encode messages, e.g., using multiplication mod p, and s^{-1} to decode. Can you see why it's hard to compute s if you know p, g, g^m , and g^n ? How could you make this cryptosystem safer? Do you see a way to "break" it?

3. Our second coding scheme is the *RSA cryptosystem*.¹ Here's how it works: You need two prime numbers p and q, compute their product m = pq, find a number b that is relatively prime to $\phi(m) = (p-1)(q-1)$, and compute an inverse c of b modulo $\phi(m)$, i.e., $bc \equiv 1 \mod \phi(m)$. You keep all of this private except for the numbers m and b which you make public (in particular, your friends know m and b). To send you a message d, your friend encodes it as

$$e = d^b \mod m$$
.

You can decode your friend's message by computing

$$d = e^c \mod m$$
.

Explain why this decoding works. What makes this cryptosystem safe? How could you make it safer? What would one need to break it?

- 4. Stein 2.10, 2.30, 3.4, 3.5.
- 5. Write down a precise statement for each definition we have given this week. For each definition, give an example and a non-example.

¹The RSA cryptosystem is named after its discoverers Ron Rivest, Adi Shamir, and Leonard Adleman.
